[\[Attachment 74934 - Click to enlarge\]](#)

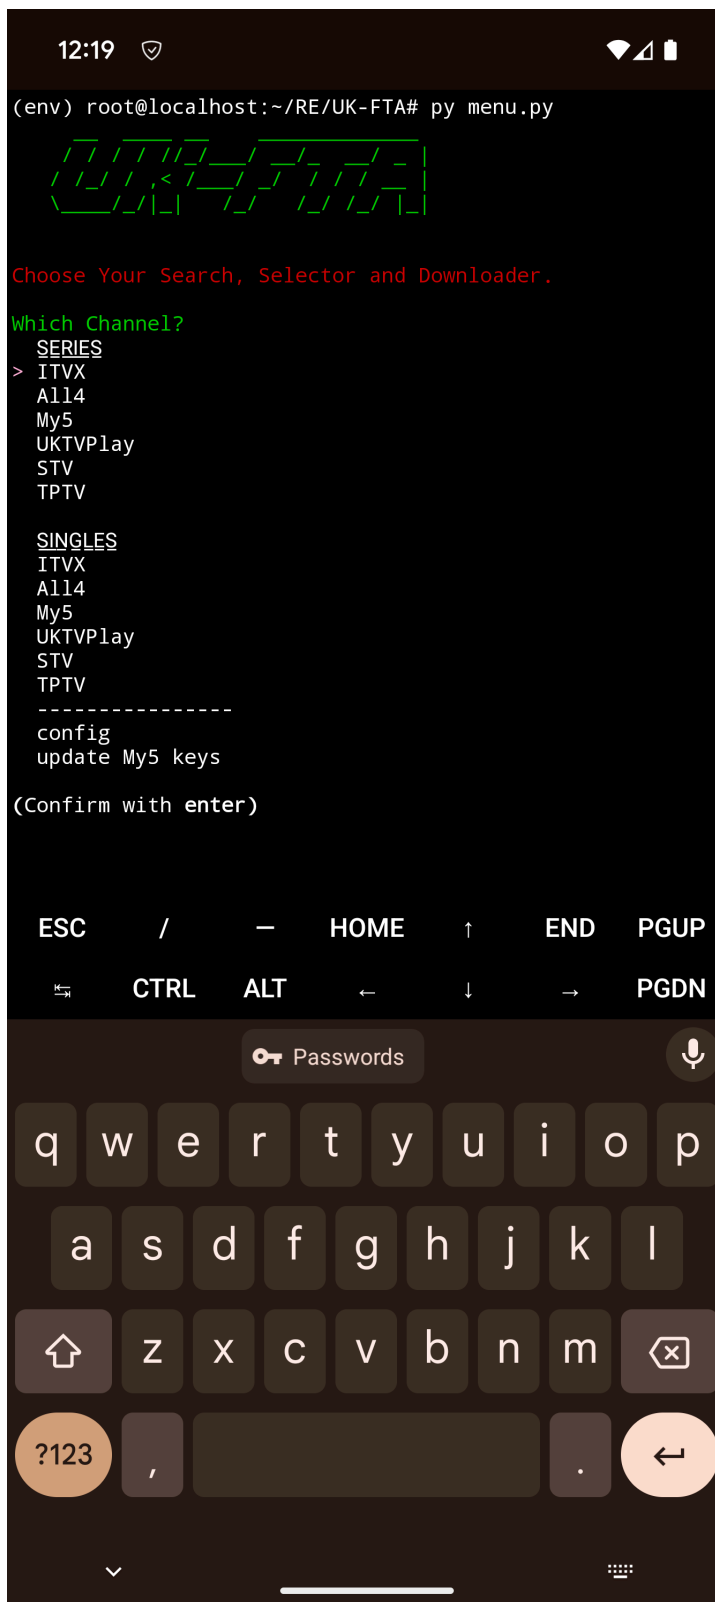

A while ago I posted about [decrypting on your Android Phone](#). That post is still sound but it deals with key finding, using WKS-KEYS, downloading with [yt-dlp](#) and decrypting, mainly by hand. We now have scripts and N_m3u8DL-RE to play with

The above linked post is a little out of date now we have N_m3u8DL-RE as a fast all-in-one downloader. But scripts, generally, are more available to do the grunt work of downloading.

[\[Attachment 74937 - Click to enlarge\]](#)

Such as running get_iplayer

[Attachment 74938 - Click to enlarge]

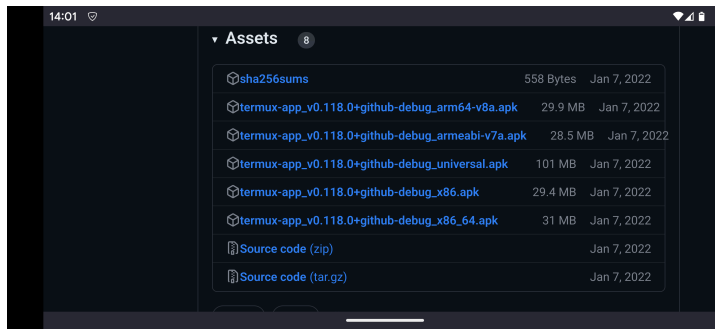

Or other software

With a friendly interface it is now child's play to download to and decrypt videos to your phone. This post is about setting up software on your phone that allows Ubuntu, a variety of Linux, to run scripts as if it were a PC.

Termux is a phone app that allows a Linux emulator to run on your phone. It cannot change anything on your phone system other than files in the storage area that you can see with a file manager - the area known as /sdcard/.

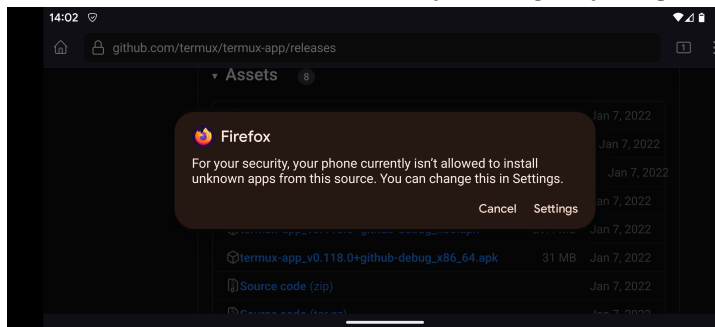

Termux may be installed by getting the apk from github <https://github.com/termux/termux-app/releases> and selecting arm.v8.

If your phone will not handle arm.v8 or x64 then N_m3u8DL-RE will not work on earlier systems. (A Google Pixel 4XL can be had quite cheaply.)

[Attachment 74933 - Click to enlarge]

So visit Termux on github and download the apk to your phone. Use your phone's file-manager and click on the download to install it. You may need to give system permission to do this.

[Attachment 74939 - Click to enlarge]

I'm going to reproduce here an edited version of the steps to get Termux running on your phone from the VH link at the start

There are several places to get help installing Termux - start looking on reddit.com/r/Termux or <https://discord.gg/termux-641256914684084234>

To avoid confusion in the description below - phone code looks like this:-

This is written in the terminal emulator screen (Termux)

And your PC instructions typed in a command or terminal window look like this:-

Code:

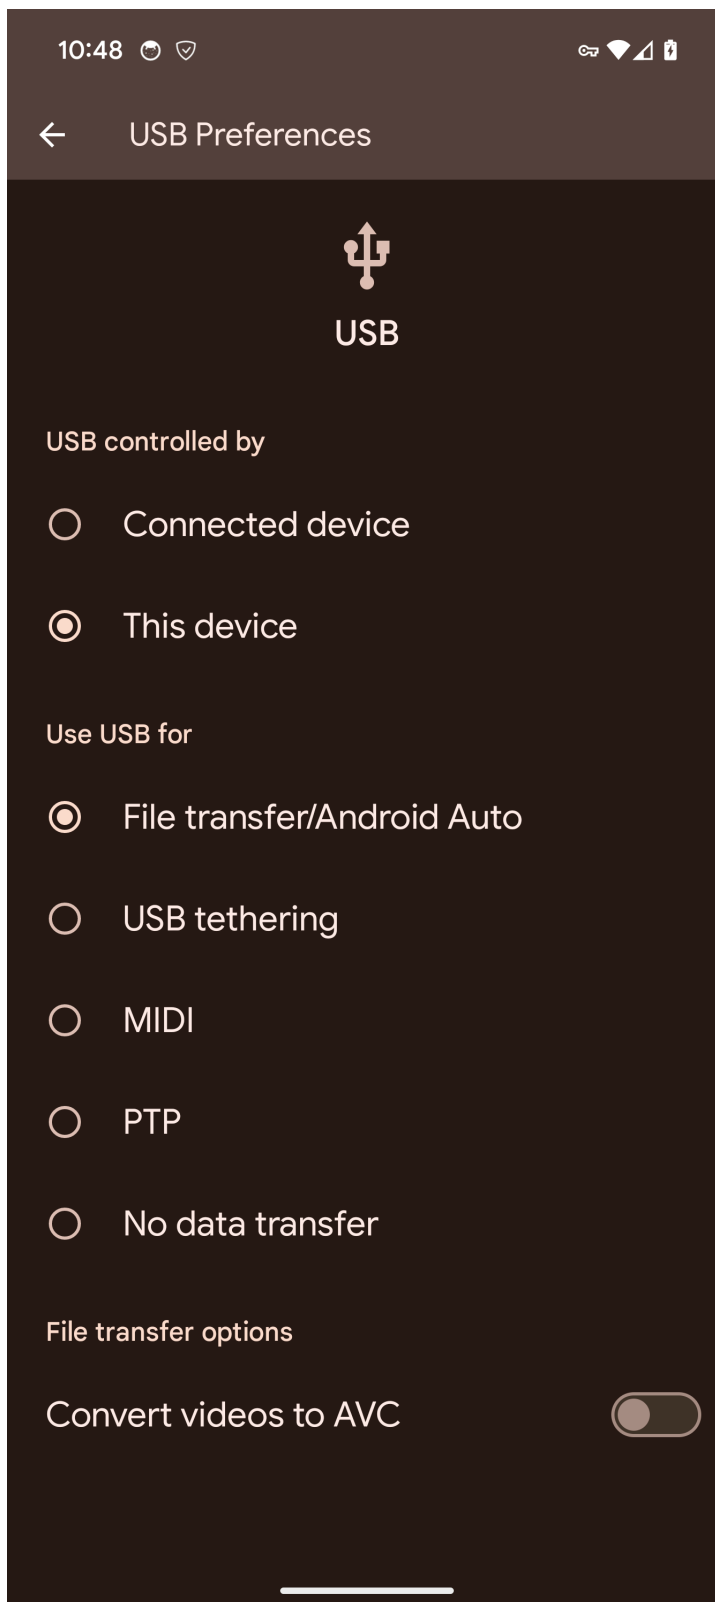

This is typed on your PC

First you'll want to set up house in Termux:

```
pkg update & upgrade
termux-setup-storage
pkg install openssh
```

You now have a basic Termux working environment.

Getting stuff on your phone is easy. cable connect and set-up permission for file transfer.

[Attachment 74940 - Click to enlarge]

Android Debug Bridge (adb) is an Android tool supplied by Google. Getting adb set up on your PC is harder on Windows than Linux but [use this guide to get adb running](#) **IMPORTANT** you do need to **setup developer permissions on your phone** so if you need to do that read the XDA article carefully!

Code:

```
adb push ./<some folder> /sdcard/
```

sends the whole directory and sub-folders to your phone. We will use this later.

From here on we need proper access to your phone, from a command window or terminal on your PC, so we can work more easily. We will set up Termux to allow Secure Shell connections (ssh) and openssl

was installed to Termux above earlier to facilitate this.

On your phone and in the Termux app set up an access password:-

```
passwd
```

find out who you are:

```
whoami
```

will respond with something like u0_a100

start the secure shell daemon on your phone with

```
sshd
```

Find out your phone IP address :-

```
ifconfig
```

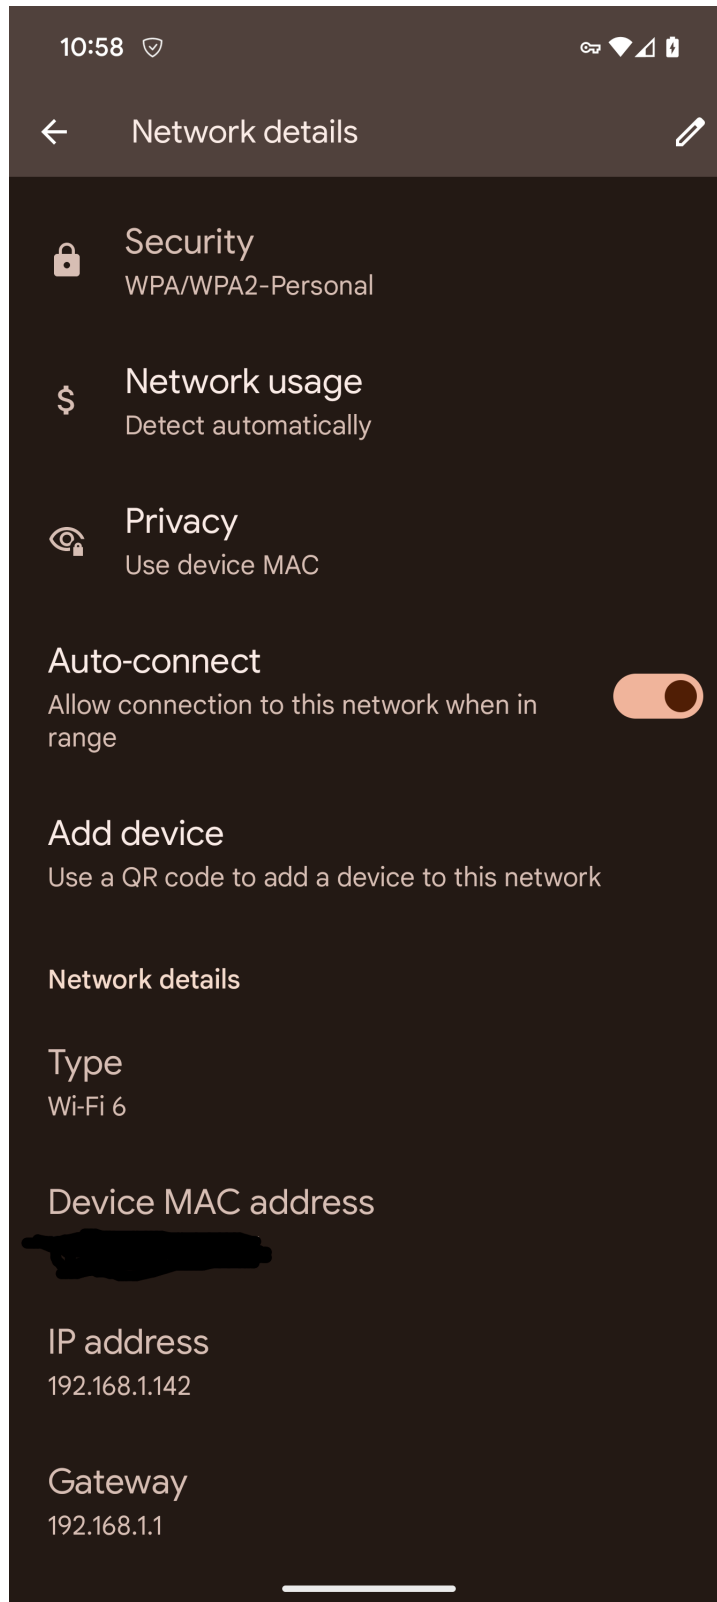

Look through the resulting text displayed and find four-triple numbers probably 192.168.1.xxx and make a note of this for use next and in the future.

Now from your PC

Code:

```
ssh -p8022 u0_a100@<phone-IP-address>
```

You will need your local network address:-

[Attachment 74966 - Click to enlarge]

Find your phone's local network address is in Network Settings.

Now you have a link to your phone it is more easy to configure.

But if you would prefer a wireless connection, after you've setup adb on your PC

Code:

```
adb devices
```

adb should respond with

Code:

```
* daemon not running; starting now at tcp:5037
* daemon started successfully
```

```
List of devices attached
39141XXXG00EC1 device
```

to use a wireless connection type this to tell adb to use a wireless port

Code:

```
adb tcpip 5555
```

and connect wirelessly with

Code:

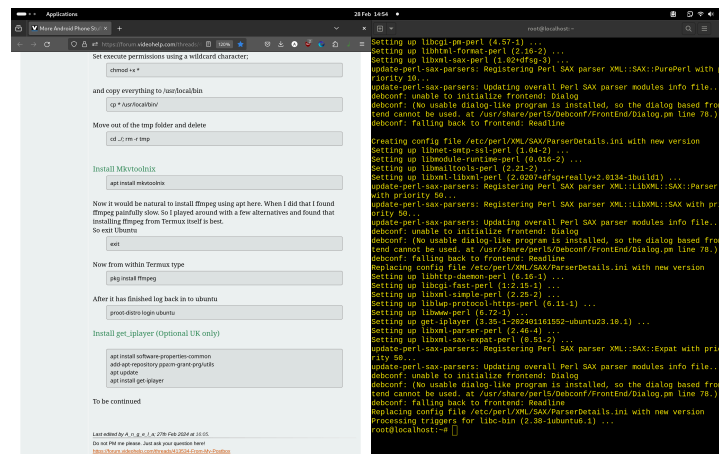

```
adb connect <phone-IP-address>:5555
```

the cable may now be removed. This feature is recent (few years) and older Android devices may not work.

This may help if you get stuck:- <https://www.makeuseof.com/use-adb-over-wifi-android/>

NOTE: from now on TYPING IS IN A TERMINAL ON YOUR PC LINKED TO YOUR PHONE
anything you type here will execute on your phone.

It makes sense to have both this guide and your terminal (command) window open as below. In this manner cutting from the guide and pasting in terminal is child's play.

[Attachment 77312 - Click to enlarge]

We will be setting up a Proot using an Ubuntu Linux Distribution. Proot and I quote Google "PRoot allows one to mix transparently the emulated execution of guest programs and the native execution of host programs in the same file-system namespace." that basically means we can run Ubuntu within Termux and Ubuntu may use any Termux programs as its own.

```
pkg install proot-distro
```

will install the software to allow PRoot

Once complete we can use proot to install Ubuntu with:-

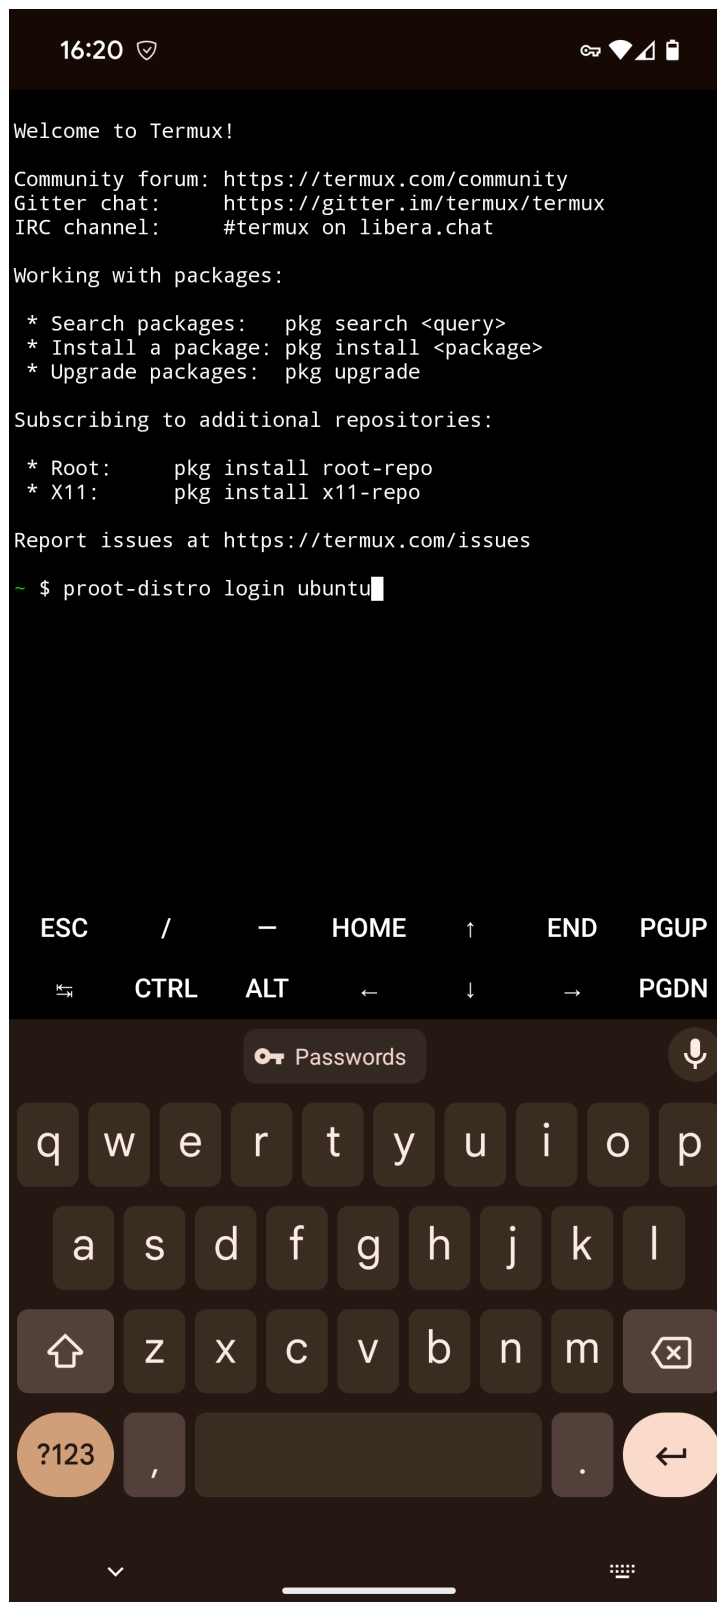

```
proot-distro install ubuntu
```

Wait while it downloads and unpacks. Once finished

```
proot-distro login ubuntu
```

will start an ubuntu session.

You can also type directly in Termux too should you wish.

[Attachment 74942 - Click to enlarge]

If you want to end your session type 'exit' to get back to Termux. You may close Termux by typing 'exit' too.

But that's enough for now part 2 will setting up Ubuntu with N_m3u8DL-RE, [ffmpeg](#) and all tools needed to download and decrypt will be along soon.

Part 2.of More Android Phone Stuff - work in progress

Picking up from:

```
proot-distro login ubuntu
```

Start from within Ubuntu to update the list of out-of-date software and upgrade

```
apt update
```

```
apt upgrade
```

Install some utilities

```
apt install wget unzip libicu-dev
```

We are currently in the /root folder of Ubuntu and we can work from here to get most of what we need.

Get N_m3u8DL_-RE note ONLY ONE version works

[Attachment 74943 - Click to enlarge]

```
wget https://github.com/nilaoda/N_m3u8DL-RE/releases/download/v0.1.5.3-beta/N_m3u8DL-RE_Bet...0230323.tar.gz
```

will download the more commng arm.v8 version Go [here](#) for others, and

```
tar -zxvf N_m3u8DL-RE_Beta_linux-arm64_20230628.tar.gz
```

will unpack to a folder N_m3u8DL-RE_Beta_linux-arm64.

All of the program files will be placed in /usr/local/bin/ in our proot distrobution of Ubuntu.

To do copy

```
cp N_m3u8DL-RE_Beta_linux-arm64/N_m3u8DL-RE /usr/local/bin/
```

We will need to give it execute permission on the system, so..

```
chmod +x /usr/local/bin/N_m3u8DL-RE
```

will do it. Anything that sits in this folder that needs to run globally will need chmod +x <filename> after placement.

Get shaka-pakager

arm.v8 version is <https://github.com/shaka-project/shaka-packager/releases/download/v3.0.1/packager-linux-arm64>

```
wget https://github.com/shaka-project/shaka-packager/releases/download/v3.0.1/packager-linux-arm64
```

will fetch it. It downloads as a binary directly.

Copy to /usr/local/bin and rename

```
cp packager-linux-arm64 /usr/local/bin/shaka-packager
```

```
chmod +x /usr/local/bin/shaka-packager
```

Get Bento Tools

create a tmp directory and move into it

```
mkdir tmp; cd tmp
```

Download Bento Tools

```
wget https://files.videohelp.com/u/301890/bento4_tools_android.zip
```

Unpack

```
unzip bento4_tools_android.zip
```

Set execute permissions using a wildcard character;

```
chmod +x *
```

and copy everything to /usr/local/bin

```
cp * /usr/local/bin/
```

Move out of the tmp folder and delete

```
cd ../; rm -r tmp
```

Install Mkvtoolnix

```
apt install mkvtoolnix
```

Now it would be natural to install ffmpeg using apt here. When I did that I found ffmpeg painfully slow. So I played around with a few alternatives and found that installing ffmpeg from Termux itself is best. So exit Ubuntu

```
exit
```

Now from within Termux type

```
pkg install ffmpeg
```

After it has finished log back in to ubuntu

```
proot-distro login ubuntu
```

Install get_iplayer (Optional UK only)

```
apt install software-properties-common  
add-apt-repository ppa:m-grant-prg/utlis
```

```
apt update
apt install get-iplayer
```

To be continued

Last edited by A_n_g_e_l_a; 11th Mar 2024 at 06:15. Reason: Updated shaka-package release to 3.01

Noob Starter Pack. Just download any Widevine media! Over 30,000 downloads for V6!.

Setting up Python and installing scripts

```
root@localhost:~/RE# get_oplayer Shetland
get_oplayer v3.34
Copyright (C) 2008-2010 Phil Lewis, 2010- get_oplayer c
ontributors
This program comes with ABSOLUTELY NO WARRANTY; for det
ails use --warranty.
This is free software, and you are welcome to redistrib
ute it under certain
conditions; use --conditions for details.

Matches:
6438:  Shetland: Series 8 - Episode 1, BBC One, m001s15g
6439:  Shetland: Series 8 - Episode 2, BBC One, m001s701
6440:  Shetland: Series 8 - Episode 3, BBC One, m001sg9m
INFO: 3 matching programmes
root@localhost:~/RE#
```

[Attachment 74955 - Click to enlarge]

get_oplayer, installed in the last part, running on an Android phone.

We are going to install python and use the env(ironment) feature. a Python Env allows conflicting modules to be installed on a system. Modules are installed into a named env(ironement) and are oblivious to anything outside. It is pretty easy to set up and take care of.

You should be inside your proot-distro , using Ubuntu and in the /root folder.
Check where you are with Print Which Directory pwd

and it should return /root. If not Change Directory

```
cd /root
```

so you are.

Now set up some sub-directories to work in.

```
mkdir -p ./RE/UK-FTA
```

will make two folders one inside the other.

cd to RE

```
cd RE
```

Install python and a couple of modules using apt

```
apt install python3 python3-venv python3-pip
```

Note this system likes to use python3 as a moniker but we can change that later.

When install is complete cd to the UK-FTA folder ready to set up a python env(ironment)

```
cd UK-FTA
```

```
python3 -m venv env
```

which makes a virtual environment called 'env;.

When complete check it is working.

```
source env/bin/activate
```

Your screen prompt should show

Code:

```
(env) root@localhost:~/RE/UK-FTA#
```

Now we are ready to install pywidevine

```
(env) pip install pyaml pywidevine
```

should now install two modules into your env. If not successful go back and check all steps to this point.

```
cd ~ # /root
mkdir -p keyblob/WVD
cd keyblob
```

Your CDM client_id.Blob and private.key are going to be copied first to your phone then into the keyblob folder.

From your PC

Code:

```
adb devices
```

should respond with device and a serial number if you set things up correctly in part 1. If not use you phone connected to your PC and find a way for file manager to copy files across to the phone's

Download folder. But note the name changes to client_id.bin and private_key.pem
If using adb move inside the folder with your blob and key on your PC

Code:

```
adb push <blob-name> /sdcard/Download/client_id.bin
```

Code:

```
adb push <key-name> /sdcard/Download/private_key.pem
```

From your phone and inside the keyblob folder

```
mv /sdcard/download/client_id.bin .
```

Don't miss the full-stop in that command! Do the same for private key

```
mv /sdcard/download/private_key.pem .
```

Create a WVD file

```
(env) root@localhost:~/RE/keyblob# ls
wvd client_id.bin private_key.pem
(env) root@localhost:~/RE/keyblob# pywidevine create-device --help
INFO:root:pywidevine version 1.5.3 Copyright (c) 2022-2023 rlapheonix
INFO:root:https://github.com/rlapheonix/pywidevine
Usage: pywidevine create-device [OPTIONS]

Create a Widevine Device (.wvd) file from an RSA Private Key (PEM or DER)
and Client ID Blob. Optionally also a VMP (Verified Media Path) Blob, which
will be stored in the Client ID.

Options:
  -t, --type [CHROME|ANDROID] Device Type [required]
  -l, --level INTEGER RANGE Device Security Level [1<=x<=3; required]
  -k, --key PATH Device RSA Private Key in PEM or DER format
                        [required]
  -c, --client_id PATH Widevine ClientIdentification Blob file
                        [required]
  -v, --vmp PATH Widevine FileHashes Blob file
  -o, --output PATH Output Directory
  --help Show this message and exit.
(env) root@localhost:~/RE/keyblob#
```

[\[Attachment 74956 - Click to enlarge\]](#)

Change the names your your blob and key in this command

```
pywidevine create-device -c client_id.bin -k private_key.pem -t ANDROID -l 3 -o WVD
```

Should complete without fuss. Now cd to the WVD folder and use 'ls' to list the file contents,
You should find a long name reflecting the origin of the CDM. We will simplify this to mbox.wvd.
Move the file to a new name start by typing mv and the first characters of the name and use auto-
complete. My key for that is 'tab'.

```
mv <wvd-filename> mbox.wvd
```

note the location /root/keyblob/WVD/mbox.wvd, if ever scripts ask where your wvd file it is
[/root/keyblob/WVD/mbox.wvd](#)

Installing optional scripts

You now have a working python environment and any scripts that work on a PC should work here.
The only change needed to note that N_m3u8DL-RE is an earlier version and --no-logs in the
N_m3u8DL-RE command will crash it. Edit out --no-log

In any folder where you suspect N_m3u8DL-RE is being use of this command will find files that need
editing

```
grep -r --no-log .
```

will show if any files have the command present and will need editing.
Nano is the editor

```
nano <file_path/filename>
```

Any scripts should work now that use N_m3U8DL-RE. yt-dlp can be installed too. (My UK- FTA installs yt-dlp using pip)

```
cd /root/RE/UK-FTA
```

```
unzip UK-FTA.zip
```

```
(env) root@localhost:~/RE/UK-FTA# pip install -r requirements.txt
```

```
pip install -r requirements.txt
```

```
python3 menu.py
```

```
(env) root@localhost:~/RE/UK-FTA# python3 menu.py
```

```
      /_/_/_/_/_\   _/_/_/_\_|  
     /_/</_/_/_/_/_\   |_  
    \_\_|/_/_/_/_/_\   |_|
```

```
cd /root
```

```
nano .bashrc
```

(Note the full stop)

We are going to add a few aliases such that we can type just one letter to change to a UK-FTA and call python3 just by typing 'py'.

```

GNU nano 7.2 .bashrc
*)
;;
esac

# enable color support of ls and also add handy aliases
if [ -x /usr/bin/dircolors ]; then
    test -r ~/.dircolors && eval "$(dircolors -b ~/.dircolors)" || eval "${dircolors-}"
    alias ls='ls --color=auto'
    #alias dir='dir --color=auto'
    #alias vdir='vdir --color=auto'

    alias grep='grep --color=auto'
    alias fgrep='fgrep --color=auto'
    alias egrep='egrep --color=auto'
fi

# some more ls aliases
alias ll='ls -lF'
alias la='ls -A'
alias l='ls -CF'

# Alias definitions.
# You may want to put all your additions into a separate file like
# ~/.bash_aliases, instead of adding them here directly.
# See /usr/share/doc/bash-doc/examples in the bash-doc package.

if [ -f ~/.bash_aliases ]; then
    . ~/.bash_aliases
fi

# enable programmable completion features (you don't need to enable
# this, if it's already enabled in /etc/bash.bashrc and /etc/profile
# sources /etc/bash.bashrc).
#if [ -f /etc/bash_completion ] && ! shopt -oq posix; then
#    . /etc/bash_completion
#fi
alias u='cd /root/RE/UK-FTA/'
alias py='python3'
alias env='cd /root/RE/UK-FTA; source env/bin/activate'
alias r='cd /root/RE'
alias d='deactivate; echo "Closing Python env"'

```

[Attachment 74959 - Click to enlarge]

paste this to the very end of the .bashrc file

```

alias u='cd /root/RE/UK-FTA/'
alias py='python3'
alias env='cd /root/RE/UK-FTA; source env/bin/activate'
alias r='cd /root/RE'
alias d='deactivate; echo "Closing Python env"'

```

Ctrl+s saves and ctrl+x exits nano editor.

Now logout from Ubuntu and login again to activate the aliases we have set

```
exit
```

drops you back to a \$ prompt in Termux

```
proot-distro login ubuntu
```

re-enters Ubuntu now type env and the prompt changes to show env and you've also changed to UK-FTA folder.

This time 'py' can be use instead of python3 and use auto-complete to avoid typing too much.

On your phone screen look for the two opposing arrows in the region just above the keyboard - these arrows are the auto-complete key.

The other extra Termux functions above the phone keyboard have up-down/left-right controls for

moving a cursor. CTRL is sticky and waits for the next key C or D, or whatever, to allow emulation of a PC keyboard. Everything you might need is there for keyboard entry. Scripts ideally would try to minimise keyboard entry.

```
root@localhost:~# env
(env) root@localhost:~/RE/UK-FTA# py menu.py
```

UK-FTA should run 'out-of-the-box as all configs follow the install pattern of placing and naming files. If you made changes then maybe the config file will need editing in nano

Any videos downloaded by UK-FTA will appear in the sdcard Download folder so it is accessible to apps like VLC or Casting apps.

Let me be clear any python script should be able to run on Ubuntu. If you use scripts that have need of module imports first create a new folder from RE move into that new folder and create a NEW venv env1 and activate with source env1/bin/activate and install any modules those scripts need. Deactivate when finished.. In this way may author's scripts may happily exist on a system each not affecting the other.

Finally. Casting to a TV is an obvious use. Or using your phone to watch videos during a commute to work. But is is also a backup to download video if your main machine may be out of action.

That's all I know.

ESC / - HOME ↑ END PGUP
⌫ CTRL ALT ← ↓ → PGDN

[on-screen keyboard with 'Passwords' label]
```

[Attachment 74984 - Click to enlarge]

[Attachment 74983 - Click to enlarge]

Close env if open: We can use the shortcut 'd' or 'deactivate'

```
d
cd /root
mkdir FV
cd FV
wget https://github.com/stabbedbybrick/freevine/archive/refs/heads/main.zip
unzip main.zip
mv main freevine-main
```

renaming main to freevine-main makes it less anonymous.

Next set up an env for the new scripts first move into the scripts top level folder and then create a new

env - I called mine 'frenv'

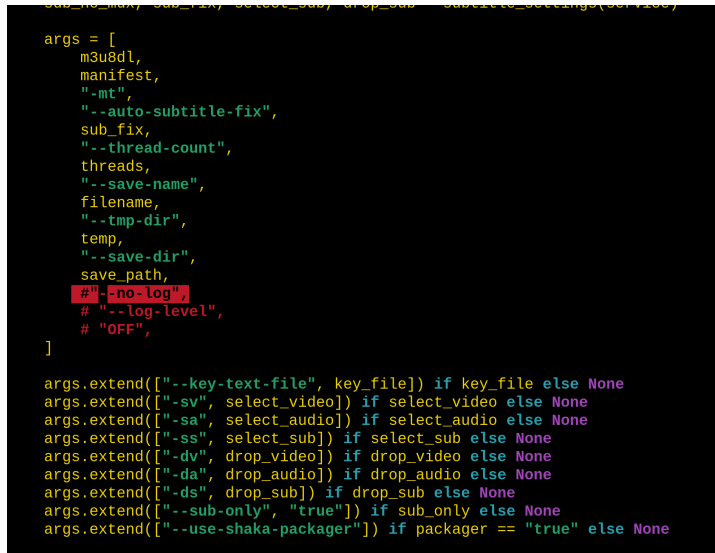

```
cd freevine-main
py -m venv frenv
source frenv/bin/activate
```

You may decide to set up another alias to start frenv from a single typed character.

There is one file that will kill N_m3u8DL-RE and needs editing out:-

```
nano ./utils/args.py
```

from within nano, CTRL +w opens search. Enter --no-log RETURN and comment out the highlighted line

```
args = [
    m3u8dl,
    manifest,
    "-mt",
    "--auto-subtitle-fix",
    sub_fix,
    "--thread-count",
    threads,
    "--save-name",
    filename,
    "--tmp-dir",
    temp,
    "--save-dir",
    save_path,
    #"-no-log",
    # "-log-level",
    # "OFF",
]

args.extend(["-key-text-file", key_file]) if key_file else None
args.extend(["-sv", select_video]) if select_video else None
args.extend(["-sa", select_audio]) if select_audio else None
args.extend(["-ss", select_sub]) if select_sub else None
args.extend(["-dv", drop_video]) if drop_video else None
args.extend(["-da", drop_audio]) if drop_audio else None
args.extend(["-ds", drop_sub]) if drop_sub else None
args.extend(["-sub-only", "true"]) if sub_only else None
args.extend(["-use-shaka-packager"]) if packager == "true" else None
```

[Attachment 74985 - Click to enlarge]

Copy your CDM to Freevine
from within freevine-main

```
cd utils
mkdir wvd
cd wvd
cp -r /root/RE/keyblob/* .
```

(Note the full stop!)

Now Freevine will run if the modules it needs are installed.

```
pip install -r requirements.txt
```

And wait for it to finish.

Freevine is a command line tool and instead of typing urls they can be, happily, pasted. Termux allows pasting anywhere below the current line and automatically places it for you. So copy a test url - I chose BBC iplayer

```
py freevine --episode S08E01 https://www.bbc.co.uk/iplayer/episodes/p01s711r/shetland?seriesId=m001s15m
```

Which downloaded and saved to a folder beneath freevine-main. I guess there will be a configuration file to tweak to save to /sdcard/ so your videos are more accessible.

So Freevine works on a mobile phone. There is a need to type and copy and paste but no insurmountable difficulties.

There is one gotcha. N_m3u8DL-RE sometimes leaves the screen so that type does not appear. Just type 'reset' and ENTER to bring back normal behaviour. This effect happens on Linux

As a side note: I noticed some windows exe files being distributed with the Freevine package.

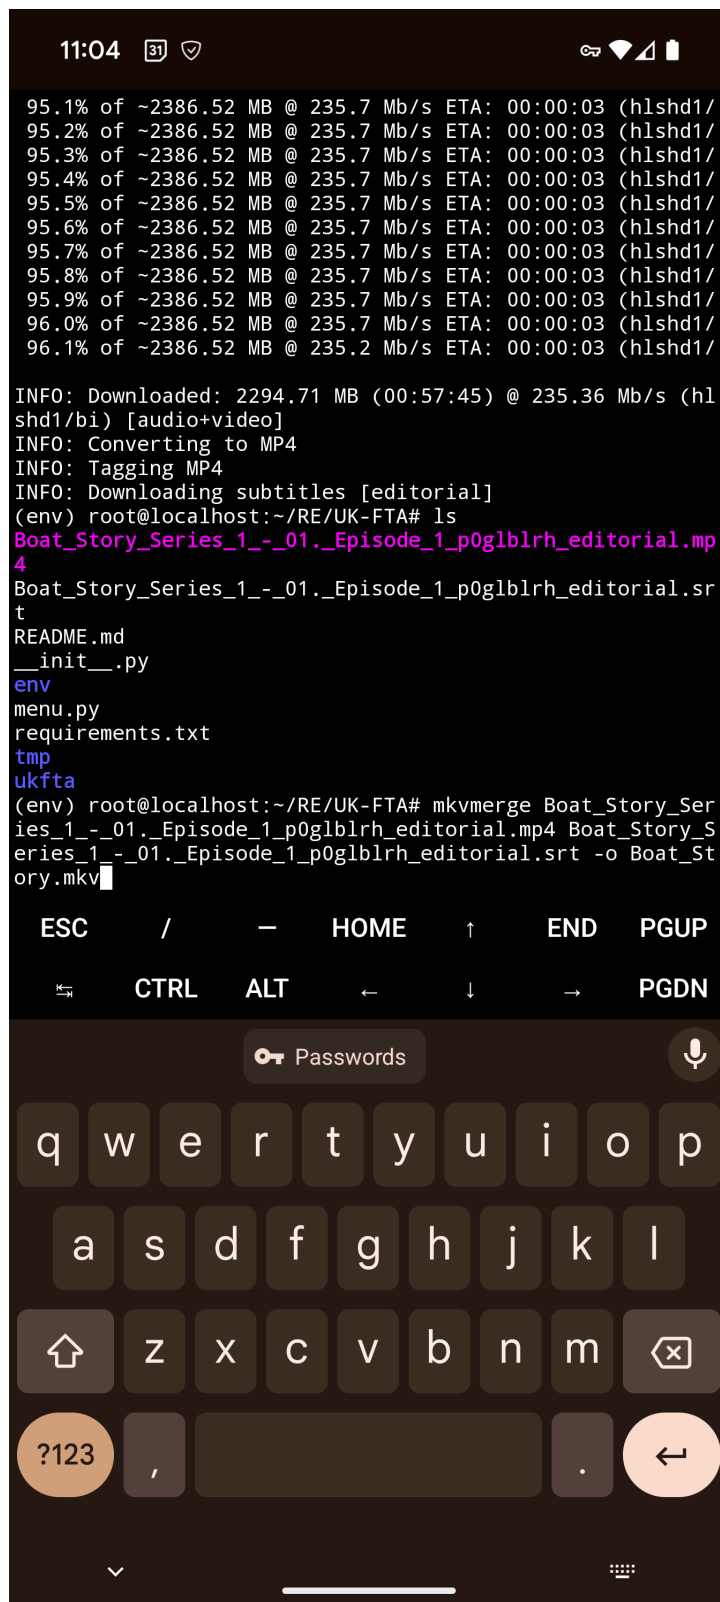

```
(frenv) root@localhost:~/FV/Freevine-main# tree | grep '.exe'
├── executable
│   ├── lexer.cpython-311.pyc
│   ├── lexer.py
│   └── lexers
├── lexer.cpython-311.pyc

│   └── gcodelexer.py
├── cli-32.exe
├── cli-64.exe
├── cli-arm64.exe
├── cli.exe
├── gui-32.exe
├── gui-64.exe
├── gui-arm64.exe
└── gui.exe
```

[Attachment 74986 - Click to enlarge]

Windows users be careful.

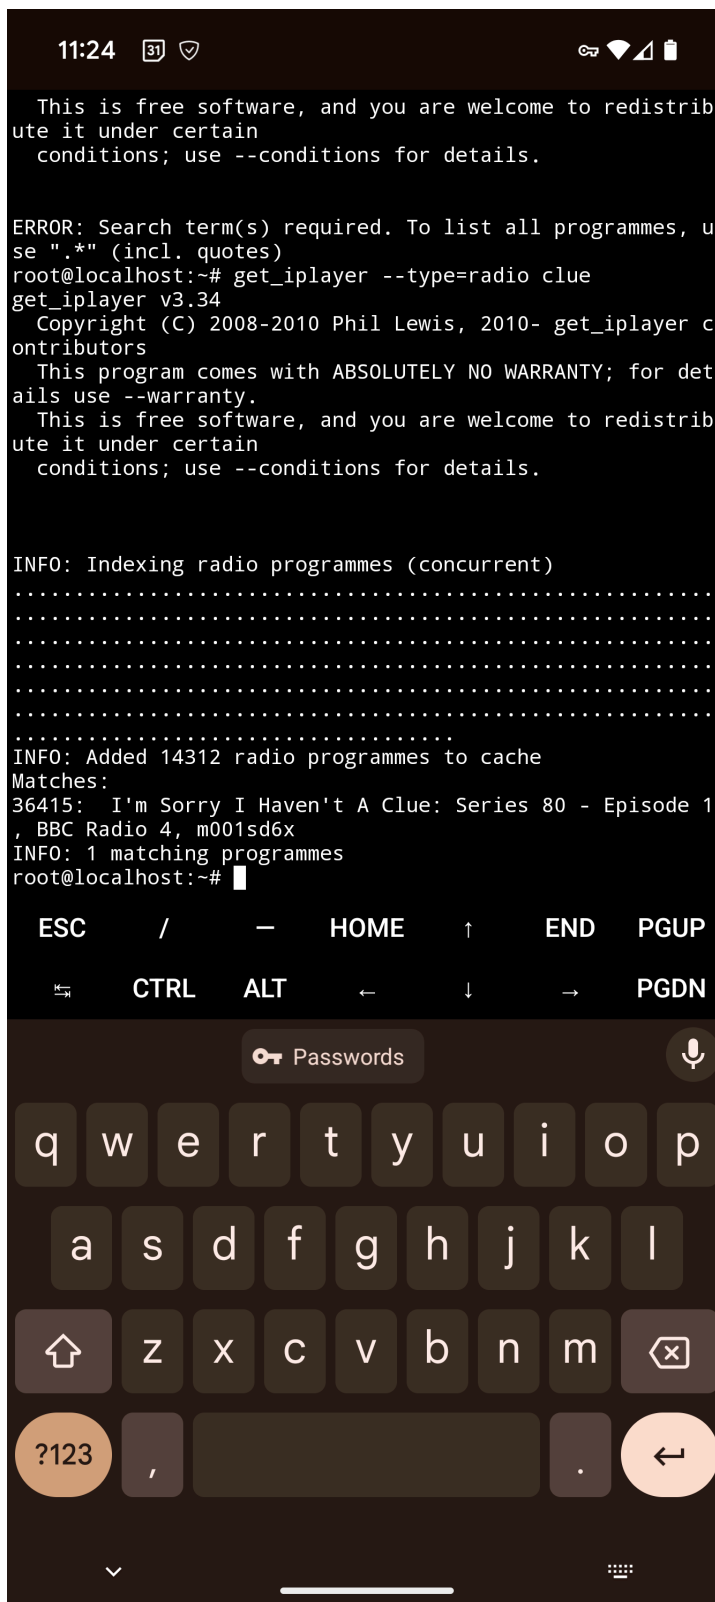

Get_iplayer

I thought I would have issues with get_iplayer but it does what it does on a mobile phone very well.

[Attachment 74987 - Click to enlarge]

As well as downloading video get_iplayer will fetch radio broadcasts too.

[Attachment 74988 - Click to enlarge]

Finally!! My install uses 2.21 Gb of space on my phone. You'll be wise to set Termux's 'App Battery Usage' to unrestricted to allow it to work unhindered.

In use I had a clash with the keyword `env` set as an alias in `.bashrc` . I solved it by renaming the alias to `envo`. Happy Days.

Many use-cases really. With my phone nearby it is sometimes more convenient than firing up the laptop. I imagine some might like fast wifi at work to do their download. Casting something you want to watch without adverts but not keep - so a quick download and immediate cast to the TV would work well. Use while travelling, use while someone else uses the home computer. Kids favourite cartoons for that family posh-restaurant meal to keep them a little quieter. Loads of uses if you want. None obligtory

This is very good A_n_g_e_l_a.

I need to digest all of this as I'm not a big phone user other than talking on it and WhatsApp. I can see the benefits though.

I'm not sure FTA needs a BBC downloader. There are tools already out there and there is no encryption. So anyone can download from the BBC without a problem.

Yt-dlp downloads 720p from a URL; get_iplayer will download at 1080p.

On a phone screen, typing is a issue, so it makes sense, to me, to use a script.

I posted this as I'd never seen anyone using get_iplayer to find download URLs for another downloader.

I really like the search bit of your FTA script, it's useful not even having to go to the website.

I'm going to add it to mine just to see if I can work out how you do it. It is great fun doing stuff like this and it is good to not be spoon-fed all the time and I really appreciate all you do for the forum.

Update to Phone-UK-FTA https://files.videohelp.com/u/301890/Phone-UK-FTA_2.zip includes BBC service and channel 5 HMAC updater is refreshed.

To use the BBC links you will need to install get_iplayer (and prove working from the command line). Installation of get_iplayer is detailed in Part two, above, as a package install in Termux

Updated to correct bug. Script was looking for program_title, bbc_channel, program_ID returned from BBC.

Sometimes BBC send program_title, extra_unexpected_data, bbc_channel, program_ID. The extra unexpected data caused the script to fail. It is now conflated with program_title

BBC search api api-key has changed. If you use the BBC links from menu.py then edit line 162 of ukft/bbc_dl/getBBCLinks.py and replace everything from and including 'apikey=' to the line end with the following:-

Code:

```
apikey=D2FgtcTxGqqIgLfBWTJdrQh2tVdeaAp&seqId=0582e0f0-b911-11ee-806c-11c6c
```

so the whole line looks like this:

```
url = f"https://search.api.bbc.co.uk/formula/iplayer-ibl-root?q={search}&apikey=D2FgtcTxGqqlgLsfBWTJdrQh2tV deaAp&seqId=0582e0f0-b911-11ee-806c-11c6c885ab56"
```

The last service addition has been through a bit of turmoil and I've written a downloader that will resume if the download fails. There is a new python module 'tqdm' to install.

Member

Feb 2022

Download progress is less pretty than the last one but I couldn't get Rich.progress to work.

I fail to remember to keep My5 HMAC keys updated. Maybe I need to do a HMAC lookup on start - maybe coming next.

A new update to sync to the PC Version. Version number jumps as a consequence.

Changes have been made to vadapav so it uses the configuration file to find its storage requirements.

Vadapav.mov is a file repository with film and TV media. Some media is 4k and a 2160 search will find it. It probably shouldn't be in an FTA list but I use it and it is convenient to access here.

Channel 4 updated with my spoof data.

Channel 5 now updates its own HMAC secret and AES keys. It will update the first time my5 is called and once every three days, but only when my5 is used. It shouldn't need intervention. (I only use my5 rarely but I got fed up running my5 and having it fail with out of date keys.)

The menu has been adjusted to reflect changes getting my5 HMAC secret and AES key.

NOTE: It is important to replace the total existing UK-FTA folder as there have been structural changes. Run config from the menu to set up storage and the wvd location. (Maybe copy those from the current config before installation of the new version?)

Requirements.txt has been updated and reduced. The need for get_iplayer, as a helper program, has been added to the top level README.md

The last phone version had 25 downloads; either that is because it had a Channel4 script that worked or because more of you are finding out just how useful it is having it on your phone. With Channel4 fixed on the PC version I'll soon know!

That is not standard behaviour, adb push <filename> /sdcard/ is expected to send filename to the base of your personal internal memory where Download is a folder.

If you want to place something in Download

adb push <filename> /sdcard/Download/

Unless you have a phone with a slot for an extra card memory, and I cannot remember how those are accessed from adb

Thank you for the tutorial A_n_g_e_l_a i have now got it all working on the phone only thing i had to do different was to copy the args.py to sdcard then edit and put it back going to do the same with config.yaml to change the download dir when I can figure out exactly what the sdcard directory is as sdcard/download is the download dir on the device not the sdcard

Drop out of lnux

cd ~/storage

ls -la
/storage/6E77-12EB/ is my sdcard name for example

Thanks again for the Tutorial

Still cant see it within the linux enviroment though
